## Perceptron

You will code the "perceptron learning algorithm". Take a look at the comments above the function. This is standard "Roxygen" format for documentation. Hopefully, we will get to packages at some point and we will go over this again. It is your job also to fill in this documentation.

```
#' Perceptron Algorithm (1957)
#'
#' This function implements the perceptron learning algorithm.
#'
#' @param Xinput
                      A matrix size n \times p.
#' @param y_binary
                      A binary vector of size n.
#' @param MAX_ITER
                      The maximum number of iterations the perceptron algorithm performs.
#' @param w
                      Intial weight vector of length p + 1 if unspecfied it will be zero.
#'
#' @return
                      The computed final parameter (weight) as a vector of length p + 1
#' @export
                      [In a package, this documentation parameter signifies this function becomes a pub
#'
#' @author
                      [Adriana Sham]
perceptron_learning_algorithm = function(Xinput , y_binary , MAX_ITER = 1000 , w = NULL){
p= ncol(Xinput)
n= nrow(Xinput)
if(is.null(w)){
   w = runif(ncol(Xinput))
}
for(iter in 1 : MAX ITER){
  for(i in 1 : nrow(Xinput)){
    x_i = Xinput[i,]
    yhat_i = ifelse(sum(x_i * w)>0, 1, 0)
    w = w + as.numeric(y_binary[i] - yhat_i) * x_i
  }
}
W
}
```

To understand what the algorithm is doing - linear "discrimination" between two response categories, we can draw a picture. First let's make up some very simple training data  $\mathbb{D}$ .

```
Xy_simple = data.frame(
  response = factor(c(0, 0, 0, 1, 1, 1)), #nominal
  first_feature = c(1, 1, 2, 3, 3, 4), #continuous
  second_feature = c(1, 2, 1, 3, 4, 3) #continuous
)
```

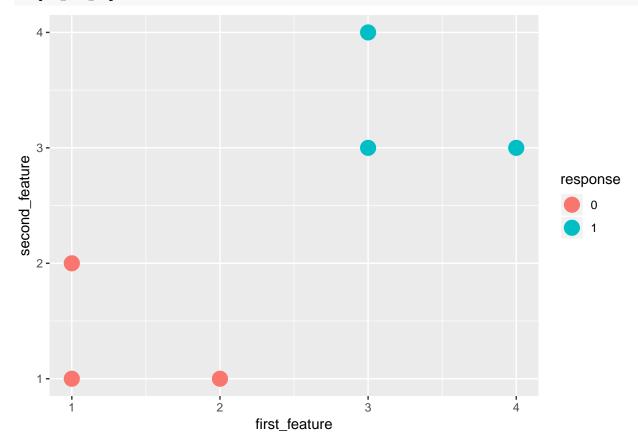

We haven't spoken about visualization yet, but it is important we do some of it now. First we load the visualization library we're going to use:

```
pacman::p_load(ggplot2)
```

We are going to just get some plots and not talk about the code to generate them as we will have a whole unit on visualization using ggplot2 in the future.

Let's first plot y by the two features so the coordinate plane will be the two features and we use different colors to represent the third dimension, y.

```
simple_viz_obj = ggplot(Xy_simple, aes(x = first_feature, y = second_feature, color = response)) +
    geom_point(size = 5)
simple_viz_obj
```

This picture gives us an idea of where the dot lie on the graph where red dots represent 0s and blue dots represent 1s.

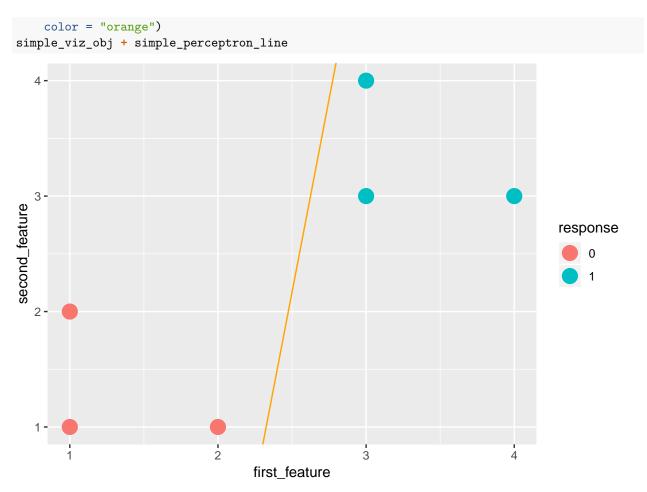

Now, let us run the algorithm and see what happens:

```
w_vec_simple_per = perceptron_learning_algorithm(
  cbind(1,Xy_simple$first_feature, Xy_simple$second_feature),
  as.numeric(Xy_simple$response == 1))
w_vec_simple_per
```

```
## [1] -8.6418626 3.9719092 -0.5941974
```

TO-DO: Explain this output. What do the numbers mean? What is the intercept of this line and the slope? You will have to do some algebra.

```
simple_perceptron_line = geom_abline(
  intercept = -w_vec_simple_per[1] / w_vec_simple_per[3],
  slope = -w_vec_simple_per[2] / w_vec_simple_per[3],
```

Although the line is cutting in between the two sets of features, but it is not cutting off in the middle of the two sets of features.

## Support Vector Machine

```
X_simple_feature_matrix = as.matrix(Xy_simple[, 2 : 3])
y_binary = as.numeric(Xy_simple$response == 1)
```

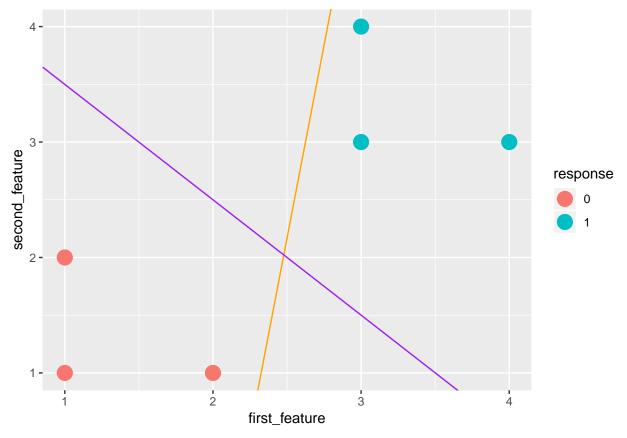

Use the e1071 package to fit an SVM model to y\_binary using the features in X\_simple\_feature\_matrix. Do not specify the  $\lambda$  (i.e. do not specify the cost argument). Call the model object svm\_model. Otherwise the remaining code won't work.

```
pacman::p_load(e1071)
Xy_simple_feature_matrix = as.matrix(Xy_simple[, 2 : 3])
svm_model = svm(Xy_simple_feature_matrix, Xy_simple$response, kernel = "linear", scale = FALSE)
```

and then use the following code to visualize the line in purple:

```
w_vec_simple_svm = c(
   svm_model$rho, #the b term
   -t(svm_model$coefs) %*% X_simple_feature_matrix[svm_model$index, ] # the other terms
)
simple_svm_line = geom_abline(
   intercept = -w_vec_simple_svm[1] / w_vec_simple_svm[3],
```

```
slope = -w_vec_simple_svm[2] / w_vec_simple_svm[3],
color = "purple")
simple_viz_obj + simple_perceptron_line + simple_svm_line
```

Is this SVM line a better fit than the perceptron?

Yes, SVM line is a better fit than the perceptron line. The SVM line (purple) divides the space of the two feature more evenly, the SVM line seems to be drawn at a equal distance from the points.

3. Now write pseucoode for your own implementation of the linear support vector machine algorithm respecting the following spec making use of the nelder mead optimx function from lecture 5p. It turns out you do not need to load the package neldermead to use this function. You can feel free to define a function within this function if you wish.

Note there are differences between this spec and the perceptron learning algorithm spec in question #1. You should figure out a way to respect the MAX\_ITER argument value.

```
#' Support Vector Machine
#
#'
   This function implements the hinge-loss + maximum margin linear support vector machine algorithm of
#'
#' @param Xinput
                      The training data features as an n x p matrix.
                      The training data responses as a vector of length n consisting of only 0's and 1'
#' @param y_binary
#' @param MAX_ITER
                      The maximum number of iterations the algorithm performs. Defaults to 5000.
#' @param lambda
                      A scalar hyperparameter trading off margin of the hyperplane versus average hinge
# '
                      The default value is 1.
#' @return
                      The computed final parameter (weight) as a vector of length p + 1
linear_svm_learning_algorithm = function(Xinput, y_binary, MAX_ITER = 5000, lambda = 0.1){
  #write pseudo code in comments
```

```
#defining the p of n columns of Xinputs
#Xinput of a combination of 1s an Xinput
#w_0 gives 0s as the vector p + 1 increases
#find first the average hinge error applying the function maxima (pmax) with the sum of 0s, subtract
#then find the maximun margin by multiplying lambda with w squared
#finally apply minima (pmin) with the sum of the average hinge error and the maximun margin
}
```

If you are enrolled in 390 the following is extra credit but if you're enrolled in 650, the following is required. Write the actual code. You may want to take a look at the optimx package we discussed in class.

```
#' This function implements the hinge-loss + maximum margin linear support vector machine algorithm of
#'
#' @param Xinput
                      The training data features as an n x p matrix.
#' @param y binary
                     The training data responses as a vector of length n consisting of only 0's and 1'
#' @param MAX_ITER
                     The maximum number of iterations the algorithm performs. Defaults to 5000.
                     A scalar hyperparameter trading off margin of the hyperplane versus average hinge
#' @param lambda
# '
                      The default value is 1.
#' @return
                     The computed final parameter (weight) as a vector of length p + 1
linear_svm_learning_algorithm = function(Xinput, y_binary, MAX_ITER = 5000, lambda = 0.1){
  #T0-D0
}
```

If you wrote code (the extra credit), run your function using the defaults and plot it in brown vis-a-vis the previous model's line:

```
svm_model_weights = linear_svm_learning_algorithm(X_simple_feature_matrix, y_binary)
my_svm_line = geom_abline(
    intercept = svm_model_weights[1] / svm_model_weights[3], #NOTE: negative sign removed from intercept
    slope = -svm_model_weights[2] / svm_model_weights[3],
    color = "brown")
## Error in -svm_model_weights[2]: invalid argument to unary operator
```

## Error in eval(expr, envir, enclos): object 'my\_svm\_line' not found

Is this the same as what the e1071 implementation returned? Why or why not?

simple\_viz\_obj + my\_svm\_line

4. Write a k=1 nearest neighbor algorithm using the Euclidean distance function. Respect the spec below:

```
#' This function implements the nearest neighbor algorithm.
#' @param Xinput
                      The training data features as an n x p matrix.
#' @param y binary
                      The training data responses as a vector of length n consisting of only 0's and 1'
#' @param Xtest
                      The test data that the algorithm will predict on as a n* x p matrix.
                      The predictions as a n* length vector.
#' @return
nn_algorithm_predict = function(Xinput, y_binary, Xtest){
  retur=rep(NA,nrow(Xtest))
  best_sqd_distance = Inf
  i_star = NA
   for (i in 1 : nrow(Xtest) ){
     for(index in 1:nrow(Xinput)){
        eucl = sqrt(sum((Xinput[i,] - Xtest[i,])^2))
```

```
if (eucl < best_sqd_distance){
    best_sqd_distance = eucl
    i_star = i
        retur[i]=y_binary[i_star]
} }
best_sqd_distance= Inf
}
retur
}</pre>
```

Write a few tests to ensure it actually works:

```
#ignoring error when knitting
nntest = nn_algorithm_predict(X_simple_feature_matrix, y_binary, X_simple_feature_matrix);
expect_equal(nntest, y_binary)
```

## Error in expect\_equal(nntest, y\_binary): could not find function "expect\_equal"

We now add an argument d representing any legal distance function to the nn\_algorithm\_predict function. Update the implementation so it performs NN using that distance function. Set the default function to be the Euclidean distance in the original function. Also, alter the documentation in the appropriate places.

```
euclidean_metric = function(x_1,x_2){
  ((x_1 - x_2)^2)
nn_algorithm_predict_d = function(Xinput, y_binary, Xtest, d=euclidean_metric){
  prediction = c(rep(NA , nrow(Xtest)))
  i_star = c(rep(NA, nrow(Xtest)))
  for(k in 1 : nrow(Xtest)){
    best sqd distance = Inf
    for(i in 1 : nrow(Xinput)){
      total dsqrd = 0
      for (j in 1 : ncol(Xinput)) {
        dsqd = euclidean_metric(Xinput[i,j], Xtest [k,j])
        total_dsqrd = total_dsqrd + dsqd
      if(dsqd< best_sqd_distance){</pre>
        best_sqd_distance = dsqd
        istar[k] = i
      }
    prediction[k] = y_binary[i_star[k]]
 }
  prediction
}
```

For extra credit (unless you're a masters student), add an argument k to the nn\_algorithm\_predict function and update the implementation so it performs KNN. In the case of a tie, choose  $\hat{y}$  randomly. Set the default k to be the square root of the size of  $\mathcal{D}$  which is an empirical rule-of-thumb popularized by the "Pattern Classification" book by Duda, Hart and Stork (2007). Also, alter the documentation in the appropriate places.

```
#TO-DO --- extra credit for undergrads
```
